Project 2: CI/CD pipeline basics

Prepared by:

Onuabueke Martina Chiemezu

Date:

12th July, 2026

Introduction

This project focused on learning the fundamentals of Git and GitHub, which are essential tools used in modern software development and DevOps. The project introduced version control concepts, repository management, commit history, and remote collaboration using GitHub. Through a series of practical exercises, I learned how to track changes, manage project history, and synchronize local repositories with remote repositories on GitHub.

Project Objectives

At the end of this project, I was able to:

- Understand what Git is and why version control is important.
- Differentiate between Git and GitHub.
- Configure Git for first-time use.
- Create a local Git repository.
- Track project changes using Git.
- Create commits.
- View repository history.
- Connect a local repository to GitHub.
- Push projects to GitHub using SSH authentication.

What is Git?

Git is a distributed version control system used to track changes in files and source code over time. It enables developers to record project history, collaborate with team members, and restore previous versions when necessary.

Why is Git Important?

Git helps developers:

- Track changes to files.
- Collaborate with other team members.

- Restore previous versions of a project.
- Maintain a complete history of code changes.
- Manage software projects efficiently.

Git vs GitHub

- **Git** is a version control system installed on a local computer.
- **GitHub** is a cloud-based platform used to host and share Git repositories online.

Environment Setup

Operating System:

Ubuntu 24.04.4 LTS running on Windows Subsystem for Linux (WSL)

Tools Used

- Ubuntu Terminal
- Git
- GitHub
- SSH
- Windows 11
- Visual Studio Code (optional if you used it)

Git Version

`git --version`

Output:

`git version 2.43.0`

Configure Git

Objective

To configure Git with my username and email address.

Commands

```
git config --global user.name "Chieme20"git config --global user.email
"chiemezuomartina@gmail.com"
```

```
git config --global init.defaultBranch maingit config --list
```

```
martina@DESKTOP-RJ7LRA1:~/git-project$ git config --global --list
init.defaultbranch=main
martina@DESKTOP-RJ7LRA1:~/git-project$ git config --global user.name "Chieme20"
martina@DESKTOP-RJ7LRA1:~/git-project$ git config --global user.email "chiemezuomartina@gmail.com"
martina@DESKTOP-RJ7LRA1:~/git-project$ git config --global init.defaultBranch main
martina@DESKTOP-RJ7LRA1:~/git-project$ git config --global --list
init.defaultbranch=main
user.name=Chieme20
user.email=chiemezuomartina@gmail.com
martina@DESKTOP-RJ7LRA1:~/git-project$
```

Git requires every commit to contain the author's identity. Configuring the username and email ensures that all commits are correctly attributed.

Real World Application

Before working on projects, developers configure Git so every commit records who made the changes.

Task – Initialize a Git Repository

Objective

To create a new Git repository for tracking changes to a project.

Commands Used

```
mkdir git-project
cd git-project
git init
ls -la
```

The `git init` command initializes a new Git repository by creating a hidden `.git` directory. This directory contains all the metadata and version history that Git uses to track changes in the project.

Real-World Application

Developers and DevOps engineers use `git init` to begin version-controlling new projects. From that point on, Git can monitor file changes, maintain history, and support collaboration with other team members.

Initialize a Git Repository

To initialize a new Git repository and prepare a project for version control.

Command

git init

```
/home/martina/git-project
martina@DESKTOP-R37LRA1:~/git-project$ git init
hint: Using 'master' as the name for the initial branch. This default branch name
hint: is subject to change. To configure the initial branch name to use in all
hint: of your new repositories, which will suppress this warning, call:
hint:
hint:   git config --global init.defaultBranch <name>
hint:
hint: Names commonly chosen instead of 'master' are 'main', 'trunk' and
hint: 'development'. The just-created branch can be renamed via this command:
hint:
hint:   git branch -m <name>
Initialized empty Git repository in /home/martina/git-project/.git/
martina@DESKTOP-R37LRA1:~/git-project$ ls -la
total 0
drwxrwxr-x 1 martina martina 512 Jul 10 03:47 .
drwxr-x--- 1 martina martina 512 Jul 10 03:44 ..
drwxrwxr-x 1 martina martina 512 Jul 10 03:47 .git
martina@DESKTOP-R37LRA1:~/git-project$ git config --global --get init.defaultBranch
martina@DESKTOP-R37LRA1:~/git-project$ git config --global init.defaultBranch main
martina@DESKTOP-R37LRA1:~/git-project$ git config --global --get init.defaultBranch
main
martina@DESKTOP-R37LRA1:~/git-project$
```

The `git init` command initializes a new Git repository by creating a hidden `.git` directory inside the project folder. This directory stores all version history, commits, branches, and configuration required for Git to track changes.

Real-World Application

Developers use `git init` when starting a new project so that every change can be tracked, reviewed, and managed throughout the software development lifecycle.

Staging Files

Objective

To prepare files for committing.

Commands

`git add README.md`

`git status`

```

-bash: martina@DESKTOP-RJ7LRA1:~/git-project$: No such file or directory
martina@DESKTOP-RJ7LRA1:~/git-project$ git branch -m main
martina@DESKTOP-RJ7LRA1:~/git-project$ git branch
martina@DESKTOP-RJ7LRA1:~/git-project$ touch README.md
martina@DESKTOP-RJ7LRA1:~/git-project$ ls
README.md
martina@DESKTOP-RJ7LRA1:~/git-project$ nano README.md
martina@DESKTOP-RJ7LRA1:~/git-project$ git status
On branch main

No commits yet

Untracked files:
  (use "git add <file>..." to include in what will be committed)
        README.md

nothing added to commit but untracked files present (use "git add" to track)
martina@DESKTOP-RJ7LRA1:~/git-project$ git add README.md
martina@DESKTOP-RJ7LRA1:~/git-project$ git status
On branch main

No commits yet

Changes to be committed:
  (use "git rm --cached <file>..." to unstage)
        new file:   README.md

martina@DESKTOP-RJ7LRA1:~/git-project$ git commit -m "Initial commit"
Author identity unknown

*** Please tell me who you are.

```

git add moves changes from the working directory into the staging area.

Real World Application

Developers use the staging area to carefully select which changes should be included in the next commit.

Create the First Commit

Objective

To create the first permanent snapshot of the project by committing the staged changes.

Commands Used

git commit -m "Initial commit"

git status

git log

```

martina@DESKTOP-RJ7LRA1:~/git-project$ git commit -m "Initial commit"
[main (root-commit) 0a684dd] Initial commit
 1 file changed, 3 insertions(+)
 create mode 100644 README.md
martina@DESKTOP-RJ7LRA1:~/git-project$

```

The **git commit** command saves the staged changes to the Git repository as a permanent snapshot. The **-m** option allows a descriptive commit message to be included. The **git status** command confirms that the working directory is clean, while **git log** displays the repository's commit history.

Real-World Application

Commits enable developers to track the evolution of a project over time. Each commit acts as a checkpoint that can be reviewed, compared, or restored if needed. This is essential for collaboration, debugging, and maintaining software.

Push the Repository to GitHub

Objective

To upload the local Git repository to GitHub using SSH authentication.

Commands Used

```
ssh -T git@github.com  
git push -u origin main
```

A terminal window showing the command 'git push -u origin main' being executed. The output shows the process of enumerating, counting, compressing, and writing objects to the remote repository. It also indicates that a new branch 'main' is being set up to track 'origin/main'.

```
martina@DESKTOP-RJ7LRA1:~/git-project$ git push -u origin main  
Enumerating objects: 3, done.  
Counting objects: 100% (3/3), done.  
Delta compression using up to 4 threads  
Compressing objects: 100% (2/2), done.  
Writing objects: 100% (3/3), 291 bytes | 36.00 KiB/s, done.  
Total 3 (delta 0), reused 0 (delta 0), pack-reused 0  
To github.com:chieme20/git-project.git  
 * [new branch]      main -> main  
branch 'main' set up to track 'origin/main'.  
martina@DESKTOP-RJ7LRA1:~/git-project$
```

The `ssh -T git@github.com` command tests the SSH connection between the local machine and GitHub. After successful authentication, the `git push -u origin main` command uploads the local repository to GitHub and establishes the `main` branch as the default upstream branch for future pushes.

A terminal window showing the command 'git push -u origin main' being executed. The output shows the process of enumerating, counting, compressing, and writing objects to the remote repository. It also indicates that a new branch 'main' is being set up to track 'origin/main'.

```
martina@DESKTOP-RJ7LRA1:~/git-project$ git push -u origin main  
Enumerating objects: 3, done.  
Counting objects: 100% (3/3), done.  
Delta compression using up to 4 threads  
Compressing objects: 100% (2/2), done.  
Writing objects: 100% (3/3), 291 bytes | 36.00 KiB/s, done.  
Total 3 (delta 0), reused 0 (delta 0), pack-reused 0  
To github.com:chieme20/git-project.git  
 * [new branch]      main -> main  
branch 'main' set up to track 'origin/main'.  
martina@DESKTOP-RJ7LRA1:~/git-project$
```

Real-World Application

SSH authentication provides a secure and convenient way for developers to interact with remote repositories without entering credentials for every push or pull operation. It is widely used in professional software development and DevOps environments.

Checking Repository Status

Objective

To view the current state of the repository.

Command

```
git status
```

```
martina@DESKTOP-R37LRA1:~/git-project$ git status
On branch main

No commits yet

Changes to be committed:
  (use "git rm --cached <file>..." to unstage)
        new file:   README.md

martina@DESKTOP-R37LRA1:~/git-project$ git commit -m "Initial commit"
Author identity unknown

*** Please tell me who you are.
```

Explanation

The git status command displays the current state of the repository, including modified files, staged files, and untracked files.

Real World Application

Developers run git status before almost every commit to understand what has changed.

Viewing Differences

Objective

To compare changes made to files before committing.

Command

git diff

git diff compares the working directory with the most recent commit and displays all modifications.
